Abstract

ODPS adoption is entering a different phase. The strongest signals now come from commercial platforms that use the specification inside working product models, AI workflows and governed data ecosystems.

This white paper examines three cases. Alation builds its data product definitions on the Open Data Product Specification and uses an AI-powered Data Products Builder to help teams turn business questions and enterprise data into governed, machine-readable products. ^{S03} Dawiso uses ODPS 4.1 as the base standard for the product, commercial and service layer of its data product model, then exposes governed context to AI agents through MCP and Databricks integrations. ^{S06 S08} TrustRelay uses ODPS inside cross-organizational data ecosystems where producers publish products, consumers request access and governance terms travel with the product relationship. ^{S10}

The three cases reveal one common pattern: AI and distributed data ecosystems increase the value of a shared product model because machines need structured product context, not only raw data and schemas.

The cases sit at different points of the lifecycle. Alation illustrates AI-assisted creation. Dawiso illustrates governed context for AI agents. TrustRelay illustrates governed exchange across organizational boundaries. Together they show ODPS operating as a product layer between business intent, technical data, governance and machine consumers.

ODPS 4.1 defines a vendor-neutral, open-source and machine-readable data product metadata model. Its current scope includes product strategy, data access, service levels, data quality, licensing, contracts and agent-oriented access patterns such as MCP. The specification also includes an Agentic Product template that connects agent use cases with quality, SLA, contracts, licensing and named access methods. ^{S01}

Central finding. Successful adoption is visible when the standard becomes part of the operating system around the data product. That means product creation, governance, discovery, access, agent context, portability and organizational learning all reinforce the same product model.

Why These Three Cases Matter

The most useful adoption evidence is not a logo list. It is a traceable relationship between the specification and a working product capability. Each case in this paper meets that test through public vendor documentation, product pages or third-party project material. One additional Alation training detail is based on the author’s direct engagement and is identified separately in the evidence notes. ^{S14}

The cases also differ enough to test whether ODPS holds value outside one narrow implementation pattern. Alation works in enterprise data intelligence and marketplaces. Dawiso works in governed business context and agent integration. TrustRelay works in data spaces and cross-organizational collaboration. Their common use of ODPS appears in different architectures and different operating models.

Alation

Creation. AI helps produce governed data products. ODPS provides a portable, machine-readable product definition that survives the AI interaction.

Dawiso

Context. ODPS defines the product layer. MCP exposes governed context to agents, including agents working in Databricks.

TrustRelay

Exchange. ODPS describes products that move between organizations under controlled access, agreements and ecosystem governance.

Method used in this paper

This paper separates documented facts from synthesis. Vendor claims are attributed to the vendor. Third-party evidence is used where it adds independent confirmation. The analysis focuses on what role ODPS plays in each product, what operational capability surrounds it, and what the case implies for organizations adopting an agent-ready data product model.

Test	What counts as stronger evidence
Model adoption	The product definition maps to ODPS rather than mentioning the specification only in marketing material.
Workflow adoption	ODPS participates in creation, governance, discovery, access or agent workflows.
Portability	The implementation preserves or exports an open ODPS representation.
Operating adoption	Teams, customers or ecosystem participants use the product model in day-to-day work.

AI Creates the Data Product

Alation launched its Data Products Builder Agent in May 2025 to help data teams turn raw enterprise data into governed, reusable and AI-ready data products. The workflow starts from a user prompt or business question. The agent identifies relevant data, generates and documents the data product design specification, checks the result against marketplace and governance requirements, and keeps a human in the loop. ^{S03}

The important adoption signal sits underneath that workflow. Alation states that its data product definitions build on ODPS, which it describes as a YAML-based standard for open, portable and extensible metadata. The resulting product does not depend on the conversational context that created it. It leaves the agent workflow as a structured product definition that other software and consumers understand. ^{S03}

Alation’s current Data Products Marketplace continues the same direction. The company describes the marketplace as delivering machine-readable, context-rich products based on ODPS and designed for consumption by business users and AI agents. It also positions the Builder as a way to generate certified, governed and AI-ready products without code. ^{S04}

Case lesson. AI-generated product descriptions become more useful when the output follows a stable product model. The agent handles reasoning and curation. ODPS gives the result a form that persists across tools and lifecycle stages.

From Generated Output to Governed Product

Generative AI creates text easily. Enterprise data products require a durable structure around that text. Ownership, purpose, access, quality, service commitments and lifecycle status need to remain usable after the original interaction has ended. This is where the product model matters more than the prompt.

Alation's implementation connects the creation flow to a marketplace that certifies products against organizational standards for quality, ownership and compliance. Consumers then discover the approved products and request governed access. Alation explicitly treats the requester as either a person or an agent. ^{S04}

The product survives the AI interaction because its identity, context and governance are stored as structured product metadata rather than left inside generated prose.

This creates continuity across the lifecycle. The producer side uses AI to accelerate product creation. The marketplace side provides discovery and controlled access. The consumer side serves both human and machine users. ODPS acts as the common product representation that connects those stages.

Lifecycle stage	Alation capability	ODPS contribution
Intent	Business question or user prompt	Product purpose and structured context
Creation	Builder Agent identifies and packages relevant data	Portable product definition
Governance	Marketplace and governance checks	Structured quality, ownership and product metadata
Discovery	Certified product marketplace	Consistent machine-readable product description
Consumption	People, agents and data applications	Context that supports machine interpretation

The pattern fits the direction of ODPS 4.1. The specification now includes an Agentic Product template and named data access methods such as MCP or API, alongside quality, SLA, contract and licensing context. ^{S01} Alation's case shows the producer-side version of that idea. The product is prepared in a form that later machine consumers can evaluate and use.

Adoption Beyond Software

The Alation relationship extended beyond the technical product model. Alation licensed the author's Data Product Masterclass as a white-labeled training product and integrated it into customer onboarding and education. This evidence comes from the author's direct engagement with Alation. ^{S14}

This matters because data product adoption is an operating-model change. A platform might provide fields, workflows and governance controls, but teams still need a common understanding of why a data product exists, who the consumer is, what ownership means, and how product thinking differs from traditional data delivery.

Platform

Alation provides the environment for creating, governing, publishing and discovering data products.

Standard

ODPS supplies the open product structure used for portable and machine-readable definitions.

Learning

White-labeled training helps customers understand the product thinking behind the model and apply it consistently.

Public education reinforced the same model. Alation hosted a webinar with Dr. Jarkko Moilanen, Jake Magner and David Chao focused on how data products are designed, delivered and governed. The session explicitly covered using ODPS to structure products for human and machine use. ^{S05}

The Alation case therefore shows several forms of adoption at once. The specification appears in the product definition. AI participates in the creation process. The marketplace serves human and machine consumers. Customer education helps teams apply the model. That combination is stronger than compatibility at the file-format level.

Case lesson. Standards adoption becomes durable when software, operating practice and learning reinforce the same model. The specification defines the structure, the platform operationalizes it, and education makes the model usable across teams.

02

ODPS as the Product Context Layer

Dawiso takes a different route. Its Data Product Standard uses ODPS 4.1 as the base standard for the product, commercial and service layer. The same model uses the Open Data Contract Standard for contract and schema detail, and Data Mesh concepts for typed ports. Dawiso describes the result as one unified model where fields trace back to published standards and can be exported back to ODPS and ODCS with schema validation. ^{S06 S07}

The separation is useful because it makes the boundary of the product explicit. ODPS describes the identity, value proposition, access, service levels, quality, pricing, licensing and lifecycle status of the data product. The contract standard handles schema, checks, servers, roles and support behind a specific agreement. ^{S07}

Dawiso states that it adds no proprietary product-model layer of its own. That is a meaningful portability signal. The application acts as an implementation environment while the underlying product and contract semantics remain tied to open specifications. ^{S06}

Case lesson. The standard becomes infrastructure when users work through a commercial product while the product definition remains portable outside that product.

MCP Makes Product Context Operational

Dawiso also places that structured product context inside AI workflows. Its MCP capability exposes business context, metadata, lineage and semantic models through a single connection to MCP-enabled tools. The documented use cases include natural-language search, access-aware retrieval, context mapping and workflow actions. [S12](#)

The agent therefore receives more than technical metadata. The context layer includes business terms, ownership, classifications, lineage and data products. Dawiso’s own Databricks material describes the difference as one between an agent that knows table names and an agent that knows what the organization means by the business concepts around those tables. [S09](#)

MCP transports the context. ODPS gives the product part of that context a shared structure.

This distinction matters for agentic systems. Protocol access alone does not tell an agent whether a product is appropriate for a task. Product context carries the purpose, ownership, quality commitments, service levels, licensing and access information that support that decision. ODPS 4.1 models those areas in a machine-readable form and explicitly supports AI-oriented access patterns. [S01](#)

Agent layer	AI tools search, reason, request actions and create or update governed metadata.
MCP layer	A standard connection exposes tools and governed context to compatible agents.
Product context	ODPS structures the product identity, value, access, quality, service, commercial and legal context.
Technical contract	ODCS structures schema, checks, server and agreement detail.
Data platforms	Databricks, Snowflake, BigQuery, Fabric and other systems hold the underlying assets and compute.

Databricks and Two-Way Agent Workflows

In May 2026 Dawiso announced its listing in the Databricks MCP Marketplace. The integration allows agents running in Databricks workflows to access Dawiso context through MCP. Dawiso also emphasizes write-back. An agent that builds a pipeline, transforms data or creates a new asset can document that work in Dawiso within the permissions of the user running the agent. ^{S08}

The wider integration includes Unity Catalog write-back, Databricks Data Quality Monitoring integration and metadata scanning. Dawiso's September 2026 product material describes governed context flowing into Databricks agents through MCP, while access workflows and metadata updates connect back to the systems where the data lives. ^{S09}

Direction	Example	Why product context matters
Dawiso to agent	Business terms, product definitions, ownership and classifications	The agent receives meaning and governance alongside technical metadata.
Agent to Dawiso	Descriptions, new objects, business terms and documentation	The agent contributes to governed context instead of creating an isolated output.
Platform to platform	Unity Catalog metadata, lineage and quality information	The product context stays connected to the operational data environment.

Case lesson. Agent readiness is operational when structured product context participates in the same workflows where agents build, transform, discover and govern data.

03

ODPS Across Organizational Boundaries

TrustRelay, developed by Beyond Civic, places data products at the center of data ecosystems. Producers publish products, consumers discover them, and access requests include governed conditions such as purpose and duration. Beyond Civic lists the Open Data Product Specification as a metadata standard and describes its data products as using open and AI-ready industry standards. ^{S10}

This environment changes the product problem. Inside one enterprise, producers and consumers often share internal terminology, policies and tools. Cross-organizational exchange removes much of that shared context. The product description has to carry more meaning with it.

Beyond Civic's Urban Data Mesh uses the same model for municipalities, cities and regional authorities. The company describes data products as the building blocks of urban data ecosystems that supply smart-city applications, digital twins and AI tools. ^{S13}

The TriRegio Data Ecosystem illustrates the cross-border version. The initiative spans Germany, France and Switzerland and emphasizes decentralized data sovereignty, clear rules for exchange and interoperability. Beyond Civic reports that it established a cross-border data space and collected initial data products with participating organizations. ^{S11}

Governance Becomes Product Context

Cross-organizational data use creates questions that a schema does not answer. Who owns the product? What access is allowed? What service level applies? What does the product cost? How long may data be retained? Which jurisdiction governs the agreement? What happens when terms change?

TrustRelay treats those questions as part of the governed exchange around the data product. Its product material describes configurable access-request workflows, owner approval, transparent and auditable requests, usage terms and monitoring of who uses the product. ^{S10}

A Connected Urban Twins governance report provides external confirmation of this product-governance pattern. The report lists ODPS under product data cataloging and references TrustRelay in data-space governance tooling. The report also illustrates legal and operational agreement fields around data products, including subscription fees, retention, service expectations, jurisdiction and permitted use. ^{S16}

Service context

SLA, update frequency, availability expectations and operating commitments.

Commercial context

Pricing, subscription terms and conditions attached to product consumption.

Legal context

Licensing, permissions, retention, jurisdiction and contract relationships.

ODPS 4.I covers these product-level concerns through structured objects for SLA, pricing, licensing, contracts, data access and quality. ^{S01} TrustRelay shows why that breadth matters. Once products cross organizational boundaries, governance is part of the product experience rather than a separate document stored elsewhere.

Case lesson. Data spaces need a product model that travels with the data relationship. Technical interoperability gets the data across the boundary. Product context explains the conditions under which that exchange is useful, trusted and governable.

From Data Spaces Toward AI-Ready Ecosystems

TrustRelay's published release history shows continuing investment in ODPS. The product page records implementation of ODPS 3.1 in April 2025 and support for ODPS 4.0 later in 2025. Its published v26.04 roadmap lists ODPS 4.1 alongside small language models from Gemma and Granite and natural-language querying of catalogs and data products. ^{S10}

The roadmap is important because natural-language discovery becomes more useful when the underlying products already carry structured context. An AI system needs more than a table name to determine whether a product fits a task. It needs meaning, ownership, quality, access and usage conditions.

The same direction appears in Beyond Civic's broader product positioning. TrustRelay is presented as AI-ready data collaboration, while the Urban Data Mesh is positioned as infrastructure that supplies applications, digital twins and AI tools with governed data products. ^{S10S13}

Digicities provides another cross-organizational example. Beyond Civic describes its Urban Data Mesh as a protected environment where municipalities, utilities, public bodies and private actors shared both open and restricted data for sustainable urban development. ^{S12}

The AI-ready step does not replace data-space governance. It increases the value of structured governance because machines now participate in discovery and use.

The Three Patterns Side by Side

The three cases cover different parts of the same operating model. Alation concentrates on product creation and marketplace use. Dawiso concentrates on product context and agent integration. TrustRelay concentrates on governed exchange between organizations. ODPS provides the common product representation across those environments.

Dimension	Alation	Dawiso	TrustRelay
Primary pattern	AI-assisted creation	Governed agent context	Cross-organizational exchange
ODPS role	Base for data product definitions	Base standard for product, commercial and service layer	Metadata standard for ecosystem data products
AI role	Builder Agent creates and documents products	Agents retrieve and write governed context through MCP	Natural-language discovery appears in the published AI roadmap
Governance	Marketplace certification and controlled access	Ownership, terms, classification, access and context workflows	Membership, access requests, agreements and usage conditions
Portability	Open, portable product definitions	Round-trip export to ODPS and ODCS	Open metadata standard across ecosystem participants
Consumer	Business users, agents and data applications	People and MCP-enabled AI tools	Independent organizations, applications and emerging AI consumers

**Creation, context and exchange form three adoption paths.
Together they describe a full agent-ready data product lifecycle.**

None of the cases requires ODPS to replace every adjacent standard. The opposite pattern appears. ODPS defines the data product while adjacent models handle contracts, schemas, ports, platform metadata or ecosystem governance. The product standard gains value by fitting into that wider architecture.

What Successful ODPS Adoption Looks Like

The cases suggest that adoption should be assessed through observable operating behavior rather than through a declaration of support. A platform might parse an ODPS file and still leave the model disconnected from product creation, governance or consumption. Stronger adoption changes how the product is managed.

Adoption signal	Practical evidence
Product model	Core product fields map to ODPS and the implementation preserves the meaning of the specification.
Creation workflow	Teams or agents create and update products through the model rather than duplicating metadata in separate documents.
Governed access	Access, service, quality and usage context are part of product operations.
Machine consumption	Agents or applications retrieve structured context through APIs, MCP or other machine interfaces.
Portability	Product definitions remain exportable or reusable outside one vendor's internal representation.
Organizational learning	Training and operating guidance teach teams how to apply the data product model consistently.
Lifecycle management	Status, ownership, quality, SLAs, versions and retirement are managed as product responsibilities.

These signals also explain why AI-agent-first design changes the adoption discussion. Agent workflows amplify inconsistencies. A person might infer missing context from organizational knowledge. An agent relies more heavily on explicit, structured and machine-readable context. That pushes product purpose, ownership, quality, access and service expectations closer to the execution path.

Practical test. If the ODPS representation disappeared tomorrow, would product creation, governance, agent context or ecosystem exchange lose information or require rework? If the answer is yes, the standard has become part of the operating model rather than a documentation artifact.

A Practical Adoption Path

Organizations do not need to redesign every data product at once. The three cases point toward an incremental path where the product model is introduced around a bounded use case, connected to existing governance and then exposed to human and machine consumers.

- 1 Assess the current model. Identify where product identity, ownership, use cases, access, quality, SLAs, licensing and lifecycle information live today.
- 2 Choose a first operating use case. Start with a marketplace, AI agent, governed access flow, internal portfolio or data-space exchange where structured product context has clear value.
- 3 Map existing fields to ODPS. Preserve working definitions where they fit. Record gaps and use the extension mechanism only where a real domain requirement remains.
- 4 Connect adjacent standards. Keep contracts, schemas, vocabularies and platform-specific metadata in the models best suited to them. Reference them from the product where appropriate.
- 5 Expose the product to machines. Provide validated ODPS through APIs, files, sidecars or MCP-enabled workflows so agents receive the same product context as people.
- 6 Operationalize governance. Link product definitions to access requests, quality checks, service commitments, lifecycle states and ownership workflows.
- 7 Train producers and owners. Explain the product model in business terms so teams understand the purpose behind each field and obligation.
- 8 Measure use and improve. Track whether consumers find, access and reuse the products and whether agents make better decisions with the added context.

Architecture Implications for AI Agents

The three cases also clarify where ODPS sits in an agentic architecture. It does not replace the data platform, catalog, semantic model, contract standard or agent protocol. It describes the managed product around the data and gives agents structured information that those adjacent layers often do not carry.

Business intent	Objectives, use cases, value proposition and product KPIs explain why the product exists and what outcome it supports.
Product context	ODPS carries ownership, access, quality, SLAs, licensing, pricing, contracts and lifecycle information.
Semantic context	Glossaries, ontologies and semantic models explain domain meaning and relationships.
Technical context	Schemas, contracts, lineage, platform metadata and quality checks describe implementation and data behavior.
Agent access	MCP, APIs and other tool interfaces make the context and governed actions available to AI systems.

ODPS 4.1 reflects this architecture through the Agentic Product template and AI-specific access methods. The specification also supports references to reusable access, quality and SLA profiles, which helps teams centralize common governance while keeping product definitions modular. S01

Alation shows the producer side of the architecture. Dawiso shows the context and protocol side. TrustRelay shows the governed exchange side. A mature implementation often needs all three concerns, even when one platform does not provide every capability itself.

Architecture principle. Give agents the same product context that a responsible human consumer would need before selecting, accessing and using data. Keep that context structured, governed and portable.

Final Position

These three case studies show ODPS moving into real product architecture. Alation uses the specification as the basis for data product definitions within an AI-assisted creation and marketplace workflow. Dawiso uses ODPS 4.1 as the product layer inside an open standards model and exposes governed context to AI agents through MCP and Databricks. TrustRelay uses ODPS inside data ecosystems where products cross organizational boundaries under governed access and usage conditions.

The common requirement is structured product context. AI agents need that context because raw data and schemas do not explain product purpose, ownership, service commitments, access conditions or legal terms. Data ecosystems need it because independent organizations cannot rely on shared internal knowledge. Marketplaces need it because products must remain discoverable, governable and reusable across their lifecycle.

The strongest adoption signal is simple: the specification becomes part of how the product is created, governed, exchanged and consumed.

ODPS has developed in the same direction. Version 4.1 connects data products to strategy and KPIs, supports machine-readable quality and service context, links to formal contracts, models multiple access patterns, and includes a dedicated Agentic Product template. ^{S01}

For organizations considering ODPS, the next step is practical. Map the current product model, identify where agent or ecosystem use creates pressure for better context, choose one bounded implementation, and connect the standard to existing governance rather than treating it as a separate metadata exercise.

Engage. Dr. Jarkko Moilanen works with organizations on ODPS readiness, product modeling, architecture, adoption programs and hands-on implementation. A 30-minute discussion is enough to identify where ODPS fits, what needs to change and what a realistic adoption path looks like.
jarkkomoilanen.com/engage

Evidence Matrix

The matrix below separates documented product facts from the synthesis developed in this white paper. It also identifies the type of evidence behind each adoption claim.

Case	Documented signal	Evidence type
Alation	Data product definitions build on ODPS. Builder Agent generates product design specifications. Marketplace serves people and agents.	Official product announcement and current product page. S03 S04
Alation	ODPS used in customer learning and onboarding through a white-labeled Data Product Masterclass.	Author's direct engagement with Alation. S14
Dawiso	ODPS 4.1 is the base standard for the data product model. ODPS and ODCS round-trip exports remain schema-valid.	Official Dawiso help documentation. S06 S07
Dawiso	MCP exposes governed context to agents. Databricks integration supports agent read and write workflows.	Official announcement and current product material. S08 S09
TrustRelay	ODPS is listed as a metadata standard. Release history records ODPS 3.1 and 4.0, with 4.1 in the published v26.04 roadmap.	Official TrustRelay product page. S10
TrustRelay	Cross-border and municipal data ecosystems use data products, governed access and shared rules.	Official project references plus third-party governance report. S11 S12 S16

Interpretive synthesis

The creation, context and exchange model is the author's synthesis of the evidence above. The vendors do not present themselves as a coordinated ODPS architecture. The value of the comparison comes from seeing how the same open product model appears in different parts of the lifecycle.

The AI-agent-first interpretation also combines current ODPS 4.1 capabilities with the documented direction of these products. Alation already serves agents through its marketplace. Dawiso already uses MCP in Databricks agent workflows. TrustRelay's current published roadmap places natural-language interaction beside ODPS 4.1.

Source Notes and Evidence Base

S01 Open Data Product Specification 4.1 - Linux Foundation

<https://opendataproductions.org/v4.1/>

Why it matters: Defines the current ODPS model, productStrategy, data access, SLA, quality, contract and Agentic Product template used in the architectural analysis.

S02 Open Data Products Standards Family - observed adoption signals

<https://opendataproductions.org/>

Why it matters: Provides project-level context on the standards family and publicly tracked adoption signals.

S03 Alation Launches Data Products Builder Agent to Power AI-Ready Data

<https://www.alation.com/news-and-press/alation-launches-data-products-builder-agent-to-power-ai-ready-data/>

Why it matters: Documents the Builder Agent workflow and states that Alation data product definitions build on ODPS.

S04 Alation Data Products Marketplace

<https://www.alation.com/product/data-products-marketplace/>

Why it matters: Current product page describing machine-readable, context-rich products based on ODPS and consumption by both people and AI agents.

S05 Alation webinar: What Is a Data Product - and How Do You Build One?

<https://www.alation.com/resource-center/webinars/what-is-a-data-product-how-to-build-one/>

Why it matters: Public learning material linking practical data product design, the Alation lifecycle and ODPS for human and machine use.

S06 Dawiso Help - Built on open standards

<https://help.dawiso.com/actual/built-on-open-standards/>

Why it matters: States that ODPS 4.1 is the base standard Dawiso builds on and explains the use of open product and contract standards.

S07 Dawiso Help - Standards field mapping

<https://help.dawiso.com/actual/standards-field-mapping/>

Why it matters: Documents which product concepts map to ODPS and which contract concepts map to ODCS.

Source Notes

S08 Dawiso Joins Databricks Marketplace as MCP Provider for Data Catalog

<https://www.dawiso.com/news/dawiso-joins-databricks-marketplace-as-mcp-provider-for-data-catalog>

Why it matters: Documents Databricks MCP Marketplace listing, agent access to context and write-back into Dawiso.

S09 Dawiso - How Dawiso Extends Databricks Unity Catalog

<https://dawiso.com/blog-post/dawiso-databricks-unity-catalog>

Why it matters: Describes governed context for Databricks agents through MCP, access workflows and two-way integration.

S10 Beyond Civic - TrustRelay product page

<https://beyondcivic.com/de/produkte/trustrelay>

Why it matters: Documents data product catalog, governed access, metadata standards, ODPS release history and the published AI roadmap.

S11 Beyond Civic - TriRegio Data Ecosystem

<https://beyondcivic.com/en/references/triregio>

Why it matters: Provides a cross-border example centered on data sovereignty, governance, interoperability and initial data products.

S12 Beyond Civic - Digicities

<https://beyondcivic.com/en/references/digicities>

Why it matters: Documents a protected cross-organizational environment combining open and restricted data for municipal and utility use.

S13 Beyond Civic - Urban Data Mesh

<https://beyondcivic.com/solutions/urban-data-mesh>

Why it matters: Describes data products as building blocks for urban data ecosystems serving smart-city applications, digital twins and AI tools.

S14 Author primary evidence - Alation customer education

Direct engagement between Dr. Jarkko Moilanen and Alation.

Why it matters: Supports the statement that Alation licensed the author's Data Product Masterclass as a white-labeled product for customer onboarding and training.

S16 Connected Urban Twins - Practical Advisory Report on Governance

https://www.connectedurbantwins.de/app/uploads/2025/01/UMP_Practical-Advisory-Report-on-Governance_final.pdf

Why it matters: Provides third-party evidence linking ODPS to product data cataloging and TrustRelay to governance tooling in data-space architecture.

Dr. Jarkko Moilanen

AI Product Leadership from Strategy to Working Systems

Dr. Jarkko Moilanen works across AI products, data products, open standards and product portfolio management. His work connects business objectives with working AI systems, agentic architectures, machine-readable product definitions and the operating models required to manage them.

He ignited the Open Data Product Specification initiative, which later expanded into today's Linux Foundation Open Data Products standards family. The family covers individual product definitions, catalogs and portfolios, graph relationships, shared vocabulary and workflow contracts for human, platform and AI-agent use.

This white paper focuses on practical adoption. The three cases show how an open product model enters commercial software, AI workflows, customer learning and cross-organizational data exchange.
